## Introduction:

CHROMagar Orientation (CHO)/ESBL (Kanto Chemical, Japan) is a bi-plate consisting of CHO medium and CHROMagar ESBL (Fig. 1) for the differentiation and presumptive identification of clinically important gram-negative bacteria (Fig. 2) and detection of extended-spectrum  $\beta$ -lactamase (ESBL) producers (Fig. 3).

We report a rapid and efficient approach to urine cultures using CHO/ESBL medium.

Fig. 2. Colonies of selected organisms plated on CHROMagar Orientation medium

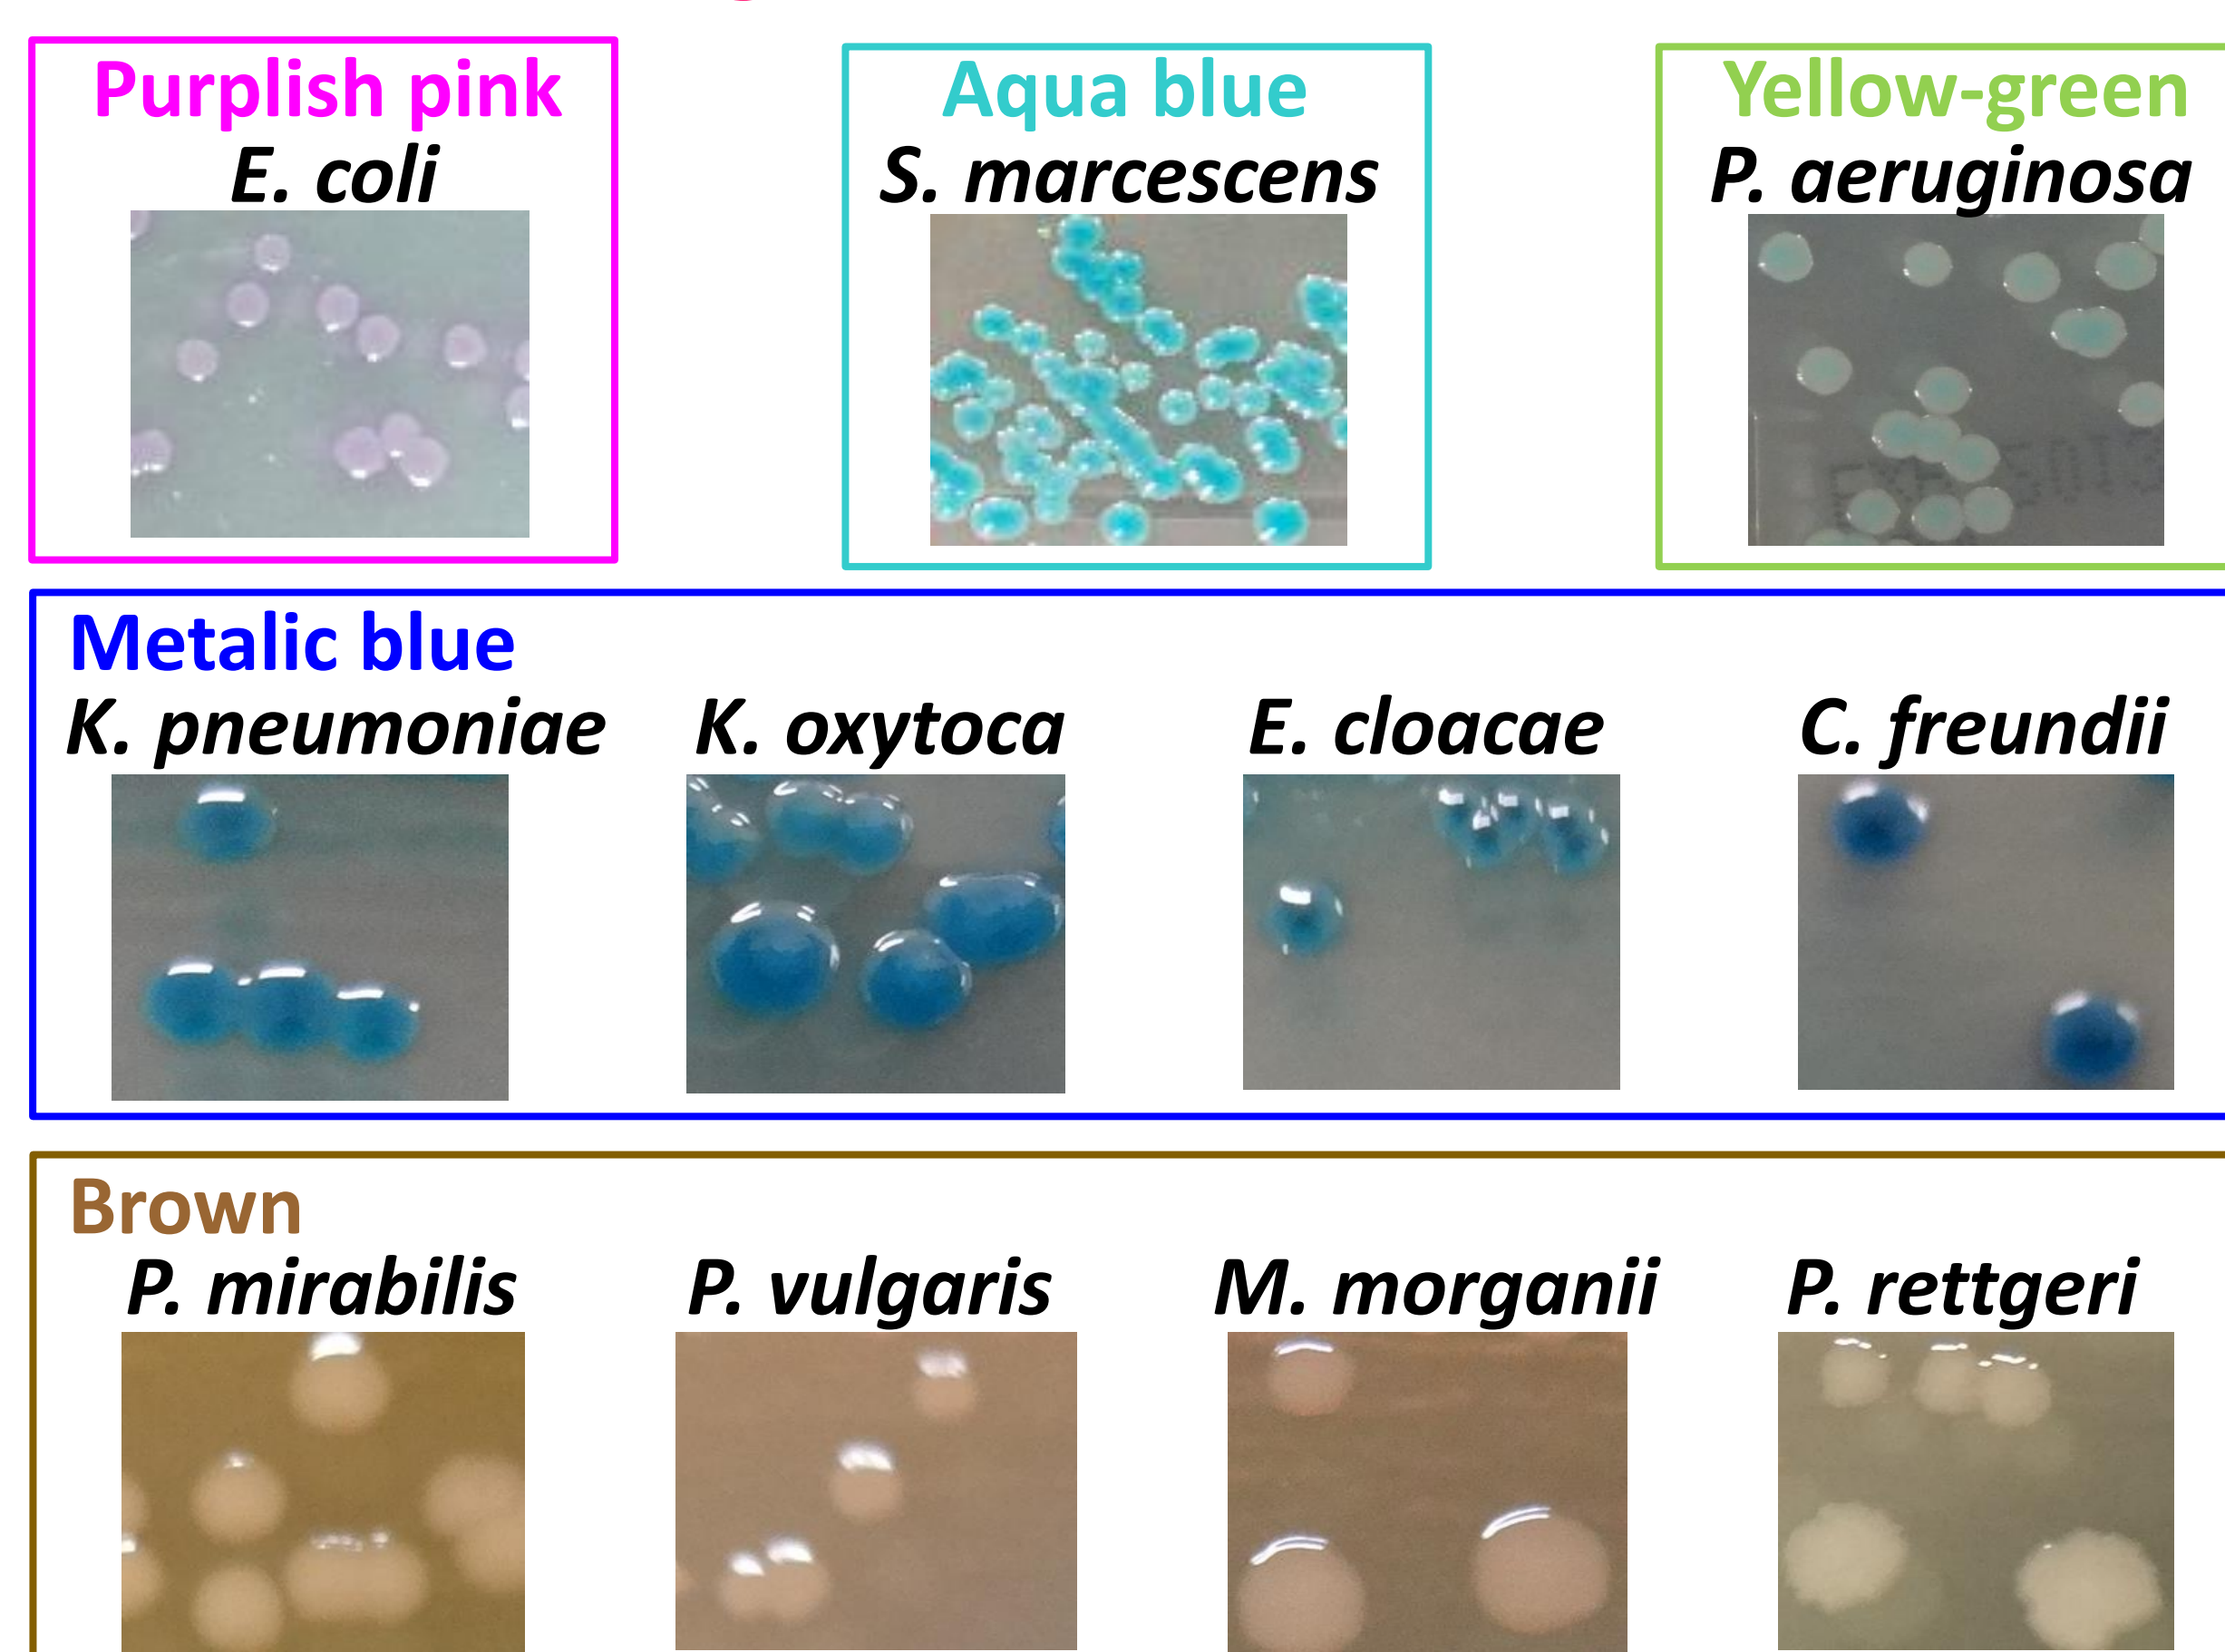

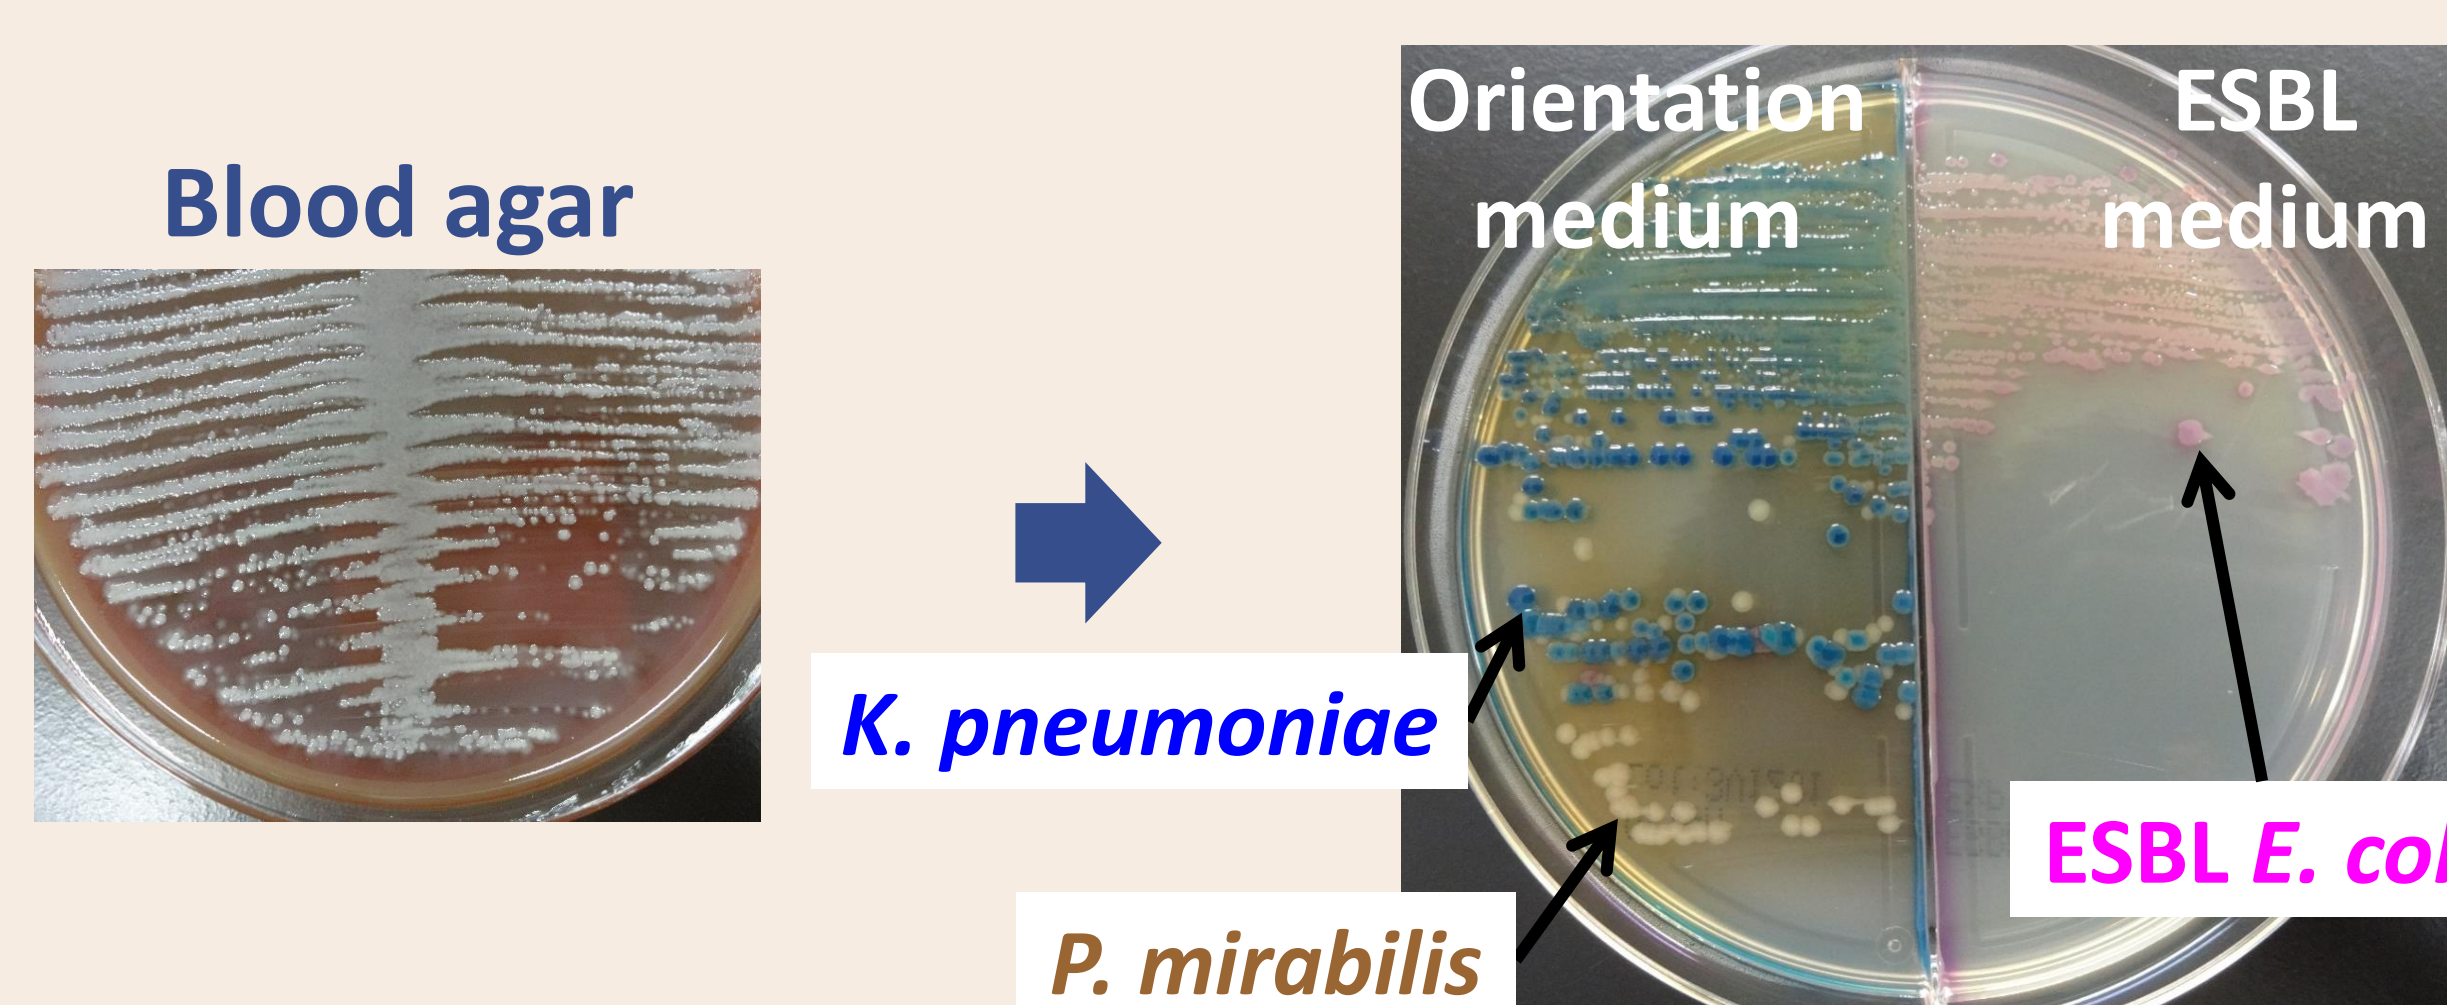

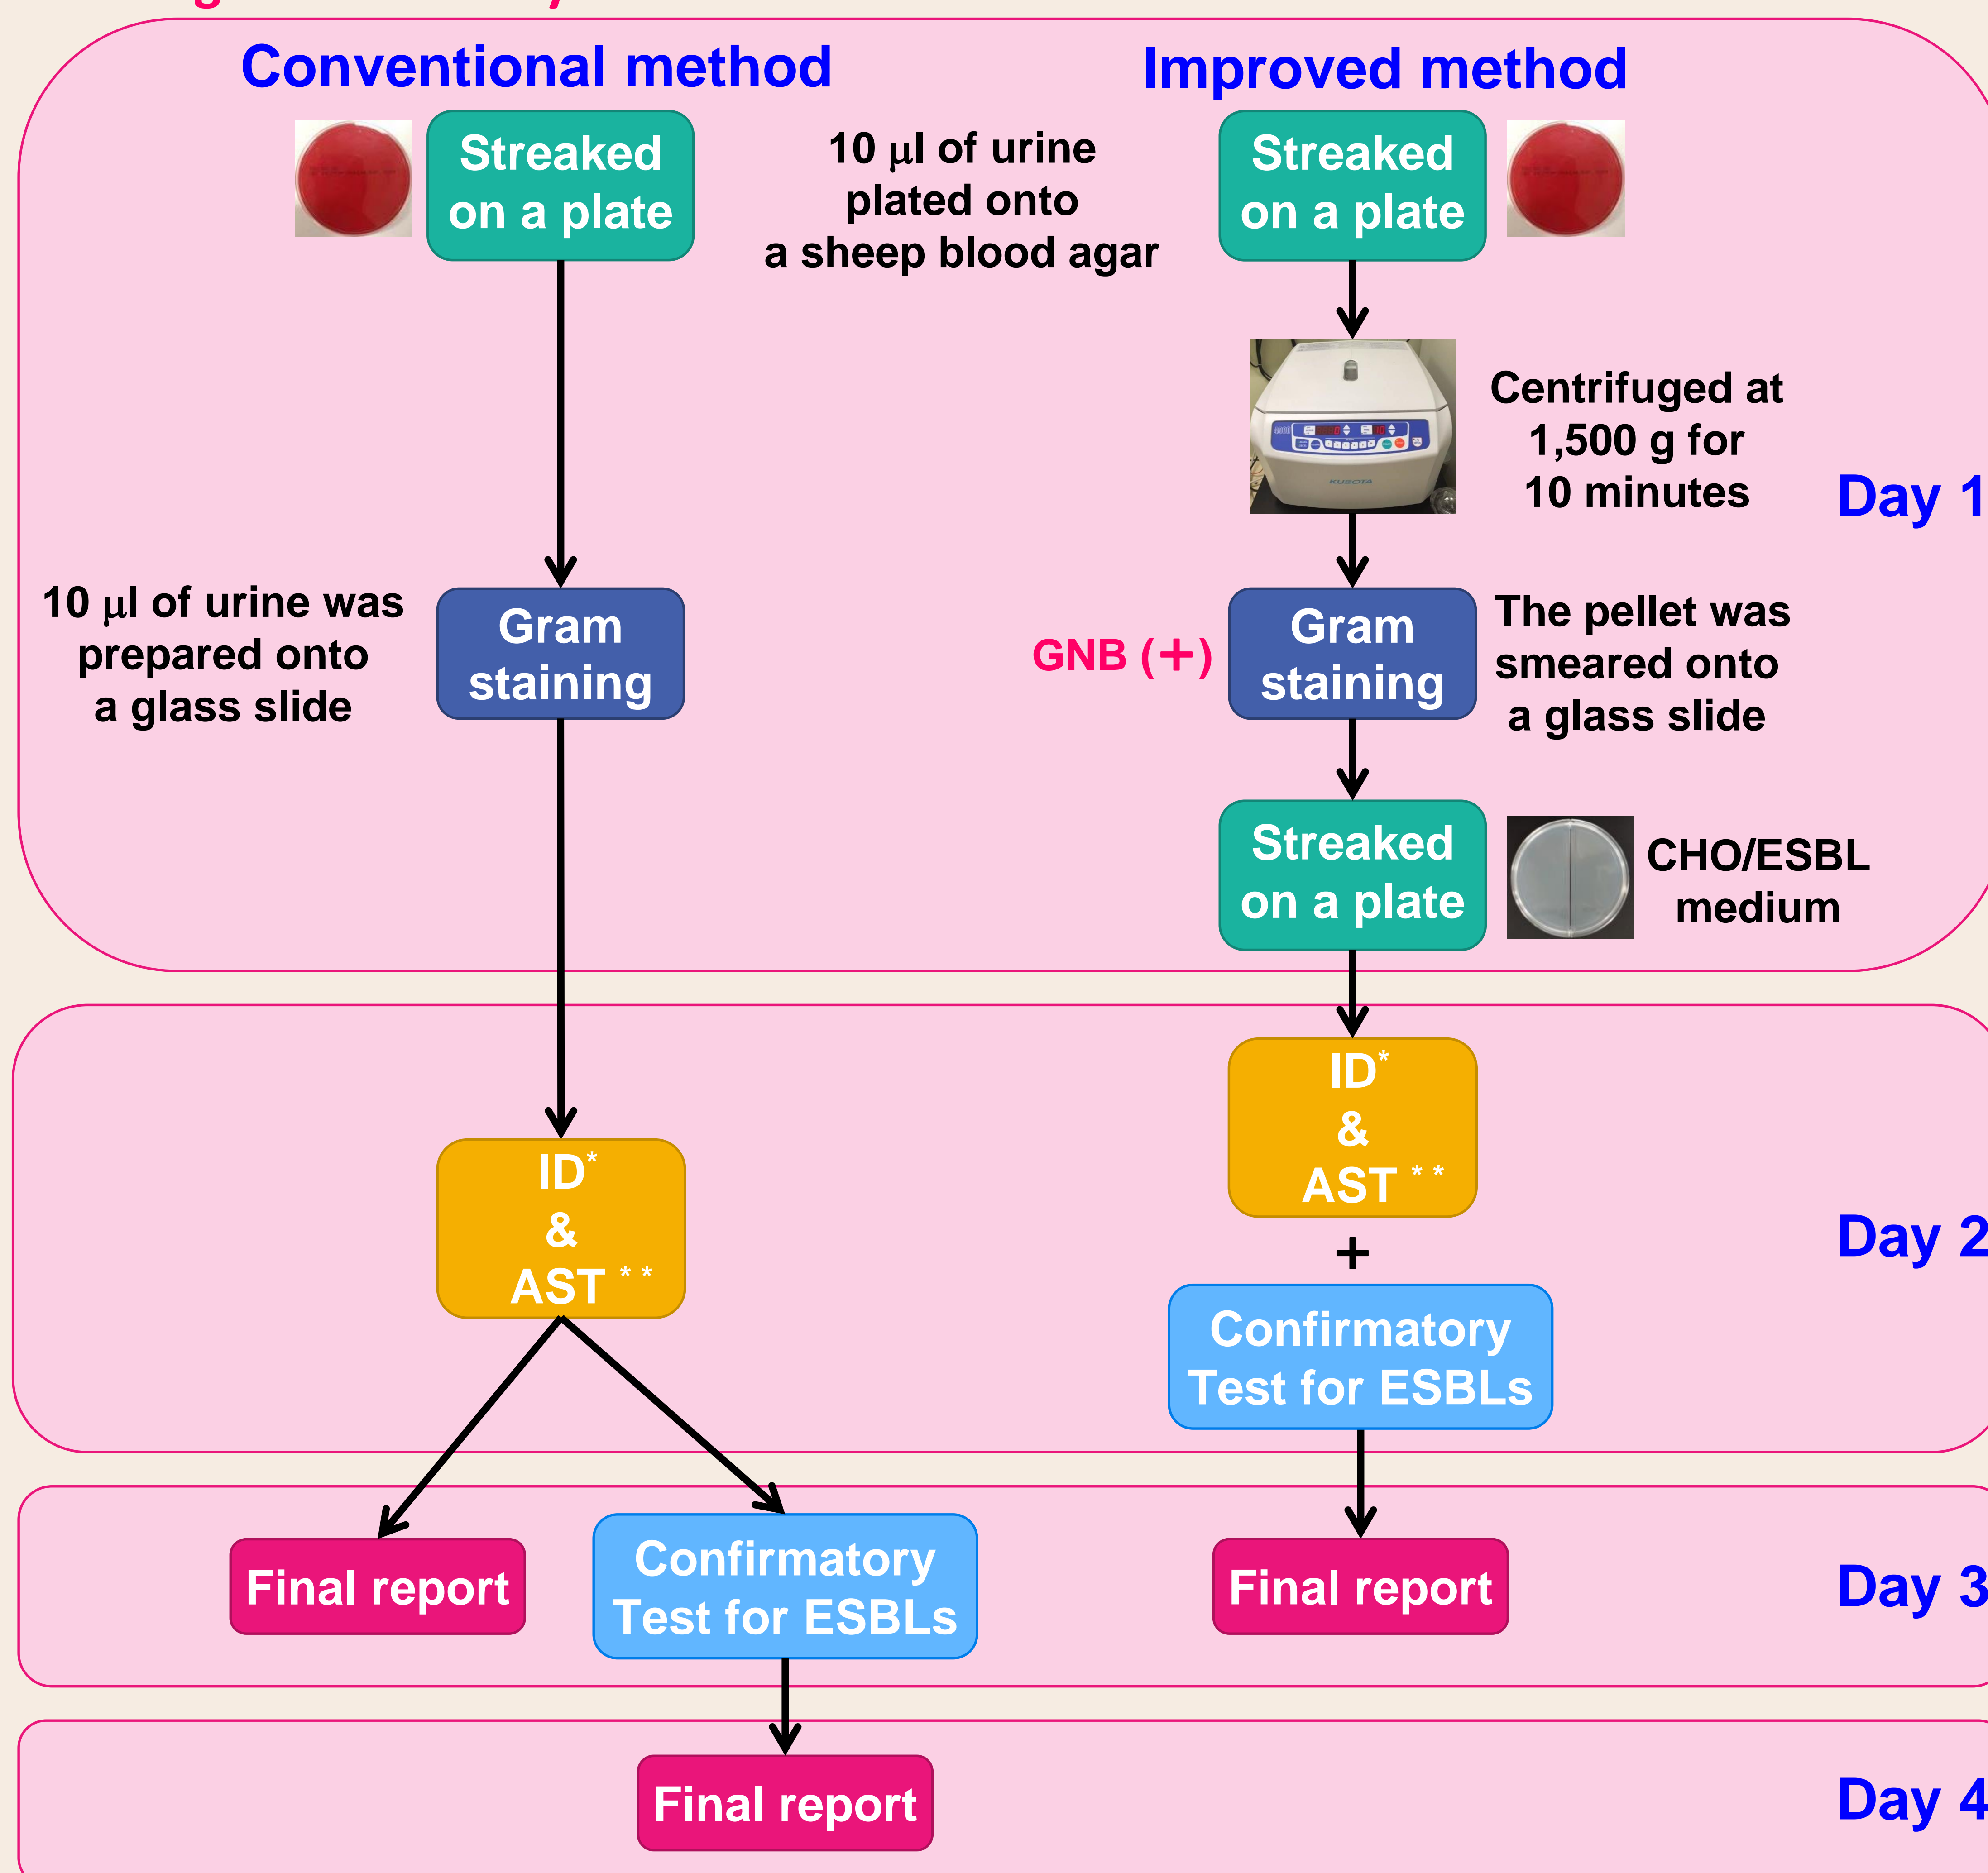

Fig. 3. GNB in mixed cultures of clinical urine sample

## Methods:

A total of 1995 urine culture results generated during the months of February, April, July and October of 2012 and 2015, were selected at random for comparison of the turnaround time. In comparing time to result between conventional urine culture and improved urine culture method, 1073 and 922 reports from 2012 and 2015, respectively, were examined. In the conventional method, 10  $\mu$ l of urine was streaked on a sheep blood agar plate. A sample of the urine was also prepared for gram-staining. In the improved method, in addition to plating of 10  $\mu$ l of urine on sheep blood agar, the urine sample was centrifuged at 1,500 g for 10 min. The supernatant was discarded and the pellet was smeared onto a glass slide for gram staining. If gram-negative organisms were observed, a CHO/ESBL medium was added (Fig. 4).

ID\* : identification, AST\*\* : antimicrobial susceptibility testing

## Results:

The mean turnaround time was 4.1 days for the conventional method compared to 3.9 days with the improved method. When ESBL-producing organisms were present in the urine specimen, the mean turnaround time was 4.6 days compared to 3.5 days with the improved method. With respect to negative urine cultures, the turnaround time was 3.2 days compared to 2.4 days with the improved method (Table 1).

Table 1. The mean time to reporting (2012 vs 2015)

|                     |      | 2012 (Conventional method)       |                   |                   |                          |
|---------------------|------|----------------------------------|-------------------|-------------------|--------------------------|
| No. of Urine sample |      | The mean time to reporting (day) |                   |                   |                          |
|                     |      | Total                            | positive cultures | negative cultures | ESBL-producing organisms |
| February            | 263  | 3.5                              | 4.1               | 3.2               | 3.8                      |
| April               | 247  | 3.7                              | 4.2               | 3.4               | 6.0                      |

| Total               | 922 | 3.0                              | 3.9               | 2.4               | 3.5                      |

## Conclusions:

The use of CHO/ESBL bi-plates allows differentiation of bacteria the day after plating and providing information on the presence or absence of ESBL-producing organisms. As this medium allows confirmatory testing of resistant organisms to be setup at the same time as antimicrobial susceptibility testing, CHO/ESBL allows reporting of resistant organisms 1 day earlier compared to conventional methodology. Furthermore, the staining of centrifuged urine sediments has reduced false negative microscopies, allowing release of final negative culture reports on the next day as well as workup of cultures with a cutoff of  $10^3$ cfu/ml for specimens showing  $>5$  WBC/hpf. The improved efficiency contributes to a rapid report with clinically useful information.
